

INTERACTIVE ELECTRONIC TELEVISION PROGRAM GUIDE  
WITH DATABASE CONFIGURABILITY

0906333 "042098  
860240" EEE9060

This application claims the benefit of United States provisional application No. 60/063,988, filed 5 November 6, 1997.

Background of the Invention

This invention relates to television systems, and more particularly, to the use of memory in interactive television program guide systems.

10 Cable, satellite, and broadcast television systems provide viewers with a large number of television channels. Viewers have traditionally consulted printed television program schedules to determine the programs being broadcast at a particular 15 time. More recently, interactive electronic television program guides have been developed that allow television program information to be displayed on a viewer's television.

Interactive television program guides, which 20 control user-interface functions, i.e. channel-selection or interactive program inspection, are typically implemented on set-top boxes. Although set-top boxes are often provided to subscribers with only the program guide application installed and a certain 25 number of pre-determined channels, cable system

operators often would like to have the capability to add more channels to their cable television channel line-up. Cable system operators may also want to install additional applications in the set-top boxes in  
5 their system when such features become available. For example, operators might wish to add application software to the set-top boxes to support a home shopping service, a home banking service, an Internet access service, or some other such service.

10 However, the amount of memory available in a set-top box is limited. Because the amount of memory required by a conventional program guide is fixed, it may not be possible to install new application software in a set-top box if the program guide application has  
15 already been installed. An example of an electronic program guide with a memory size that is fixed is shown in Lazarus U.S. Patent No. 5,652,613. Although it might be possible to reserve the needed memory capacity for the future installation of new applications by  
20 initially using a program guide with a fairly small memory requirement, such a reduced-size program guide would generally not be able to provide the same level of functionality as a full-sized program guide.

It is therefore an object of the present  
25 invention to provide a system in which the memory requirements of a program guide may be adjusted when it is desired to install additional applications.

It is a further object of the present invention to provide a system in which the memory  
30 requirements of a program guide may be adjusted to accommodate the addition of new channels to the existing channel line-up.

09063333.042098

These and other objects of the invention are accomplished in accordance with the principles of the present invention by providing an interactive

15           The database configuration record may be  
based on a look-up table arrangement that contains  
information on the preferred memory allocation to be  
used when various amounts of memory are available. If  
it is desired to change the amount of memory used by  
20 the program guide due to the installation of new  
applications, the database configuration record may be  
used by the program guide to reallocate the memory in  
the set-top box.

The database configuration record may be provided to the set-top box using a number of different techniques. For example, the database configuration record may be provided from the same source used to provide the program guide data. If desired, the database configuration record may be provided at the cable system headend. The record may be addressed to all set-top boxes controlled by a particular cable system operator, all set-top boxes in a given cable system, an individual set-top box, or other suitable grouping.

An aspect of the invention relates to the use of various levels of data storage. For each level of storage, the database configuration record may specify a desired number of hours of television program listings data to store for each category of programming, as well as a desired number of hours of descriptions. There may be a default database configuration record for each version of the program guide, for each specific type of set-top box hardware, and for each memory configuration corresponding to a specific type of set-top box hardware.

The television program guide data preferably may be divided into categories such as pay-per-view special events, pay-per-view movies, programming on premium channels, all other movies, all other sporting events, and all other series. Each data storage level specifies how the program guide is to allocate individual portions of memory for the listings and descriptions corresponding to different categories of programming.

For example, a first level (level one) in the database configuration record might indicate that the program guide should store 30 days of program listings data and program descriptions data for pay-per-view events, seven days of program listings data and five days of program descriptions data for pay-per-view movies, seven days of program listings data and 12 hours of program descriptions data for programming on premium channels, etc. For level two, which requires that less memory be used by the program guide database, the database configuration record may decrease the amount of program listings data and program descriptions data that is to be retained by the program guide for certain categories.

0906333-042000

When the program guide determines that, for the present storage level, sufficient memory no longer exists (e.g., because new channels were added to the cable television line-up or a new non-program-guide application was added to the set-top box memory), the program guide deletes all unnecessary data and changes to a program listings level and a program descriptions level that requires less memory and provides less programming data. The program guide can become aware of this shortage of memory in two different ways: 1) the installation of new channels in the line-up may alert the program guide that its available memory has

When the program guide determines that, for the present storage level, sufficient memory no longer exists (e.g., because new channels were added to the cable television line-up or a new non-program-guide application was added to the set-top box memory), the program guide deletes all unnecessary data and changes to a program listings level and a program descriptions level that requires less memory and provides less programming data. The program guide can become aware of this shortage of memory in two different ways: 1) the installation of new channels in the line-up may alert the program guide that its available memory has

5 the memory.

10 up, the program guide changes to a program listings level and a program descriptions level which uses more memory for the program guide database and can therefore provide more complete programming information to the user of the program guide.

15           The database configuration record may also be  
used to specify a default startup level. The default  
startup level ensures that whenever the set-top box is  
turned on after a power interruption, the program guide  
starts at a lower level of storage and gradually  
20 increases to the predetermined maximum program listings  
level and maximum program descriptions level for the  
program guide.

25 that the program guide continues to allocate memory properly after a power loss. Data such as program listings data and program descriptions data may be stored in volatile memory and reacquired after a power loss.

30 Further features of the invention, its nature  
and various advantages will be more apparent from the  
accompanying drawings and the following detailed  
description of the preferred embodiments.

Brief Description of the Drawings

FIG. 1 is a schematic diagram of a known interactive television program guide system.

FIG. 2 is a schematic diagram of a known  
5 interactive television program guide system according to the present invention.

FIG. 3 is a schematic diagram of a system in accordance with the present invention.

FIG. 4 is a schematic diagram of illustrative  
10 user equipment in accordance with the present invention.

FIG. 5 is a schematic diagram showing two illustrative types of user equipment in accordance with the present invention.

FIG. 6 is a schematic diagram of an  
15 illustrative set-top box arrangement in accordance with the present invention.

FIG. 7 is a schematic diagram of an illustrative memory arrangement for a set-top box in  
20 accordance with the present invention.

FIG. 8 is a table showing illustrative program listings levels in accordance with the present invention.

FIG. 9 is a table showing illustrative  
25 program descriptions levels in accordance with the present invention.

FIG. 10 is a schematic diagram of an illustrative database configuration record in accordance with the present invention.

FIG. 11 is a flow chart showing steps  
30 involved in introducing a new application to a set-top box in accordance with the present invention.

0906333-042098

FIG. 12 is a flow chart showing steps involved in reconfiguring the memory in accordance with the present invention.

Detailed Description of the Preferred Embodiments

5 In known television program guide applications, the amount of memory reserved for program guide data is fixed. An example of such a system is shown in FIG. 1. In FIG. 2, an interactive television program guide application having a variable amount of  
10 memory for program guide data according to the principles of invention is shown at step 2. The variability of the amount of memory permits the interactive television program guide to accommodate new applications (or new channel data, see FIG. 12) as  
15 necessary. Step 4 illustrates an example of the interactive television program guide adjusting to accommodate a new application. Step 6 shows the interactive television program guide allocating a reduced amount of memory for program guide data while  
20 simultaneously allocating a portion of the memory for a new application.

An illustrative arrangement for an interactive electronic television program guide system 10 in accordance with the present invention is  
25 shown in FIG. 3. Main facility 12 provides data from data source 14 to distribution facility 16 via communications link 18. Link 18 may be a satellite link, a telephone network link, a cable or fiber optic link, a microwave link, a combination of such links, or  
30 any other suitable communications path. If it is desired to transmit video signals over link 18 in addition to data signals, a relatively high bandwidth link such as a satellite link may generally be

09063333.042098

preferred to a relatively low bandwidth link such as a  
telephone line. Distribution facility 16 may be a  
cable system headend, a broadcast distribution  
facility, or a satellite television distribution  
5 facility.

The program guide data transmitted by main  
facility 12 to distribution facility 16 includes  
television program listings data (e.g., program times,  
channels, titles), program descriptions data and data  
10 for other program guide services, and may include data  
for additional services. If desired, some data may be  
provided using data sources at facilities other than  
main facility 12.

Distribution facility 16 distributes the  
15 program guide data and data for other services to  
multiple users via communications paths 20. Each user  
has user equipment 22 for displaying television  
programs, television program listings, program  
descriptions, and information for other services using  
20 an interactive television program guide. Many features  
of the interactive television program guide are  
provided by executing instructions with a  
microprocessor or similar control circuitry 54 (FIG. 6)  
within user equipment 22. Communications paths 20  
25 preferably have sufficient bandwidth to allow  
distribution facility 16 to distribute television  
programming and other video information to user  
equipment 22. Television programming and video  
information may also be distributed by distribution  
30 facility 16 over communications paths separate from  
communications paths 20.

Certain program guide functions may require  
user equipment 22 to transmit data to distribution  
facility 16 over communications paths 20 (e.g., with a

09063333.042098

cable modem, telephone modem, or other suitable return link). If desired, return data may be transmitted over separate communications paths (not shown).

An illustrative arrangement for user  
5 equipment 22 is shown in FIG. 4. The program guide may be implemented on set-top box 28. The program guide coordinates the display of television programs and television program listings information on television  
36. If desired, user television equipment 22 may  
10 include a videocassette recorder controlled by the program guide on set-top box 28 for recording selected programs.

Periodically, user equipment 22 of FIG. 4 receives television programming, video information,  
15 television program listings information, and other data from television distribution facility 16 of FIG. 3 (or from a separate data stream) at input 26. Information from the user may be transmitted to distribution facility 16 of FIG. 3 via output 27. During normal  
20 television viewing, the user tunes set-top box 28 to a desired television channel. Remote control 40 or some other suitable user input device such as a mouse, infrared keyboard, touch pad, voice recognition system, etc. may be used for interacting with the program guide  
25 and controlling set-top box 28 and television 36.

The television program guide implemented on set-top box 28 may be downloaded from television distribution facility 16 via communications paths 20. If desired, different versions of the program guide  
30 (shown as interactive television program guide application 60 in FIG. 7) may be transmitted to individually addressable set-top boxes, such as set-top boxes of different types, 23 and 24 of FIG. 5.

09063333 042098

The circuitry of set-top box 28 of FIG. 4 is shown in more detail in FIG. 6. As shown in FIG. 6, set-top box 28 contains memory 50 for data storage and control circuitry 54 (which is preferably microprocessor-based) for performing the various program guide and other set-top box functions. These functions include responding to user instructions sent via remote control 40 (FIG. 4) and responding to instructions sent by distribution facility 16 (FIG. 3) (e.g., when a new channel line-up is sent by distribution facility 16).

*Ans. a17* FIG. 5 shows an illustrative configuration of memory 50 in set-top box 28. Memory 50 contains program guide application 60, which includes a database configuration record 62 for allocating television program guide data 67 for various categories of listings information, such as television programming data 68 for category A of programming and television programming data 69 for category B of programming. Categories A and B and other such categories include special events, pay-per-view movies, sporting events, non-pay-per-view movies, or regular programs.

Additional applications 61 (e.g., an Internet browser, a shopping application, etc.) may also be contained in memory if desired. Database configuration record 62 is preferably stored in nonvolatile memory (e.g., rewritable flash memory) as indicated by dotted line 63. This ensures that program guide 60 allocates memory properly after a power loss, because memory allocation information in the nonvolatile database configuration record 62 will not be lost. Television program guide data 67 may be stored in volatile memory (e.g., random access memory), as indicated by dotted line 65. Television program guide data 67 may be

09063333 042098

5 ~~Ex 27~~ Database configuration record 62 uses program listings look-up table 64 and program descriptions look-up table 66 as guides when allocating memory between different types of television program guide data 67. When it is desired to download a new version of the database configuration record 62 to set-top boxes 28, e.g., to make more memory available to accommodate a new application, program guide 60 preferably accesses the newly introduced database configuration record 62 to determine which of the program listings levels 86 of program listings look-up table 80 of FIG. 6 and program descriptions levels 96 of program descriptions look-up table 90 of FIG. 7 coincides with the amount of memory it is desired to use for the program guide application (which relates directly to the amount of memory that will be made available for the new application).

However, when the configuration of the memory is changed, i.e., new channels are introduced into the cable television line-up or the descriptions of programming are modified (e.g., to change the size of individual descriptions, or to include pictures as part of the descriptions), a new database configuration record is preferably not required (see FIG. 12). Rather, program guide data for a new memory configuration is transmitted to the program guide without a new database configuration record, as shown in box 202. The program guide receives the program guide data for the new memory configuration, as shown in box 204. Thereafter, as shown in box 206, the

program guide reconfigures the database by checking the database configuration record for the levels corresponding to the new memory configuration and calculates the program listings level 86 and program descriptions level 96 accordingly to accommodate the new memory configuration.

lms.a37 Program listings table 80 of FIG. 8 and program descriptions table 90 of FIG. 9 show how much data is stored in memory for each category of data and for each level of memory usage. The program guide memory allocation scheme that uses the most memory for the program guide application corresponds to level zero. The program guide memory allocation scheme that uses the least memory for the program guide application corresponds to level 14. At the highest level of program guide memory usage (level zero), listings and descriptions data for special events is available for 30 days into the future. Data for pay-per-view movies, sporting events, non-pay-per-view movies, and regular programs is available for 7 days into the future. The 30 day entry in the level zero "any program" category in table 80 of FIG. 6 and table 90 of FIG. 7 indicates that any program that is more than thirty days into the future should be discarded. The highest level of program guide memory usage is suitable for arrangements in which the program guide application is the only application loaded into set-top boxes 28 and a minimum number of channels is being supported.

Whenever it is desired to remove an application other than program guide application 60 from set-top box 28 (FIG. 4), program guide application 60 may not require a new database configuration record 62. If, however, the increase in memory availability is substantial, a new database

09063333-042098

configuration record 62 may be sent from television distribution facility 16 (FIG. 3) to establish a higher level of memory usage for listings and descriptions data. This allows the user access to more program listings and descriptions information when using program guide 60.

Whenever it is desired to add an application to set-top boxes 28, database configuration record 62 may be reconfigured at television distribution facility 16 (FIG. 3) and retransmitted to set-top boxes 28. Program listings level 86 may then be changed to establish a lower level of memory usage for program guide application 60. Similarly, program descriptions level 96 may then be changed to establish a lower level of memory usage for program guide application 60. This reduces the memory required by program guide application 60 for storing program listings and program descriptions in its database, thereby making more memory available for non-guide applications.

If desired, database configuration record 62 may specify a default startup level X for program listings 70 and a default startup level Y for program descriptions 72, as shown in FIG. 10 and as indicated by arrows next to the tables of FIGS. 8 and 9. Default startup levels 70 and 72 ensure that when memory 50 in set-top box 28 is initially used to store program guide application 60, the memory is not fragmented by over-allocation of memory followed by truncation to fit a more restrictive storage level. Using default startup levels 70 and 72, data collection may start at a level that requires a relatively small amount of memory. An illustrative set of default startup levels for a system with an available storage capacity of 750 kilobytes is level zero in FIG. 8 for program listings and level six

0906333-042098

[illegible][illegible][illegible]

program descriptions look-up table 90 to calculate a  
suitable new program listings level and new program  
description level to accommodate the new application.  
The suitable program then changes either the program  
5 listings level or the program descriptions level (or  
both) (step 106). This step 106 may require a new  
database configuration record 62. The new database  
configuration record is preferably downloaded first, to  
structure the memory of the program guide 60. The new  
10 application may then be downloaded from television  
distribution facility 16 into set-top boxes 28 at step  
108.

One skilled in the art will appreciate that  
the present invention can be practiced by other than  
the described embodiments, which are presented for  
purposes of illustration and not of limitation, and the  
present invention is limited only by the claims which  
follow.

09063333 042098
